ABSTRACT

Motor innervation of trapezius and sternocleidomastoid (SCM) muscles is provided solely by the spinal accessory nerve (SAN). SAN palsy most often occurs as a result of iatrogenic injury to the nerve.

A patient, who had undergone neck dissection for thyroid cancer, presented with pain and reduced range of motion of the shoulders. Electroneuromyography revealed denervation of the trapezii and SCM muscles secondary to SAN injury. The patient was treated with a course of physical therapy (PT).

This case reminds us that a SAN lesion should be considered in the differential diagnosis of a patient presenting with shoulder pain following surgery of the neck. Even though unilateral SAN injury can eventually lead to atrophy of the trapezius, muscle asymmetry may not be obvious, especially in bilateral iatrogenic SAN injuries. In our experience, these patients benefit from PT. However, evidence to support the use of PT in the treatment of shoulder dysfunction secondary to SAN injury is insufficient; the optimum type and timing of PT requires further investigation. Development of best-practice guidelines in terms of management is necessary.

INTRODUCTION

The spinal accessory nerve (SAN), or cranial nerve XI, provides motor innervation to the trapezius and sternocleidomastoid (SCM) muscles. The trapezius aids normal scapulothoracic movement by elevating, rotating and retracting the scapula.¹ A lesion of the SAN results in denervation of the trapezius and winging of the scapula, causing shoulder pain and muscle weakness, which may in turn lead to secondary functional subacromial impingement.¹

Rarely seen, the commonest cause of SAN injury is iatrogenic and mostly occurs during surgery involving the posterior triangle of the neck, such as cervical lymph node biopsy.²

As patients mostly present with complaints of shoulder pain, a SAN lesion may be overlooked and confused with diagnoses such as subacromial impingement and rotator cuff syndrome, thus delaying the correct diagnosis.³

Here, we present a case of bilateral shoulder pain and muscle weakness following thyroidectomy.

CASE REPORT

A 41-year male patient presented with bilateral shoulder pain and difficulty in raising his arms. Four weeks previously, he had undergone a thyroidectomy and regional lymph node dissection.

Examination of the musculoskeletal system revealed bilateral drooping of the shoulders with downwards rotation and protraction of the scapulae. Passive range of motion (ROM) of the shoulders was normal in all directions. Bilateral active shoulder abduction was reduced to 60 degrees and was accompanied by pain and winging of the scapulae. Neurological examination was normal. Radiographs of the cervical spine, chest and shoulders were normal. Electroneuromyography (ENMG) revealed bilateral partial severe lesions of the SANs: widespread denervation in the upper components of the trapezius muscles with reduced recruitment of the right trapezius and bilateral SCMs (Table I). Nerve conduction studies revealed low amplitude and prolonged latency of the SAN potentials bilaterally. The patient was diagnosed with bilateral partial SAN palsy with partial re-innervation of the right SCM. A rehabilitation programme of therapeutic electric stimulation to the trapezii, ROM and progressive resistance exercises (PRE) of the neck, shoulder girdle and postural training was commenced.

Two months later, both shoulders remained protracted. Active abduction of the right and left shoulders were pain-free and limited at 80 and 60 degrees, respectively. There was no motor weakness of the SCMs or the arms.

R. & L. Serratus anterior	N	None	None	None	N	N	N	N
R. & L. levator scapulae	N	None	None	None	N	N	N	N
R. & L. Rhomboid major	N	None	None	None	N	N	N	N

MUAP= Motor unit action potential, SCM=Ssternocleidomastoid, R.= Right, L.= Left, N = Normal, Fib = Fibrillation potential, PSW = Positive sharp waves, Fasc = Fasciculations, Amp = Amplitude, Dur = Duration, Poly = Polyphasia.

Follow-up ENMG findings were consistent with bilateral partial SAN paralysis with partial re-innervation of the trapezii (Table II).

DISCUSSION

The SAN is a motor nerve which originates from the C1-C4 spinal segments. The SAN supplies motor innervation to the SCM and then innervates the trapezius via the posterior triangle of the neck. Therefore, injury of the distal segment of the SAN in the posterior triangle results in denervation of the trapezius. However, a proximal lesion resulting in denervation of both the SCM and trapezius, as seen in this case, is uncommon.

This case reminds us to include iatrogenic SAN palsy, secondary to surgery of the posterior triangle of the neck in the differential diagnosis of winging of the scapulae. Even when the SAN remains intact, demyelination or devascularisation of the nerve may still occur during surgery. Other than lymph node biopsy, cases of SAN palsy due to tumours of the jugular foramen, excision of small tumours and radical neck dissection have been reported.^{2,4}

Here, PT resulted in reduction in pain and some increase in ROM. Effectiveness of PT following SAN injury remains inconclusive; the use of orthotics for scapula support,⁵ electrotherapy⁶ and soft tissue therapy,⁷ have been suggested. Gleno-humeral joint ROM is maintained using cervical spine and shoulder exercises. Maintaining shoulder mobility reduces the risk of occurrence of secondary pathologies, such as adhesive capsulitis.⁸ PRE overloads the muscle, thus overcoming disuse atrophy and enhancing neural adaptation.⁹

A SAN lesion should be considered in the differential diagnosis of a patient presenting with shoulder pain, especially following neck surgery, as accompanying signs such as weakness of shoulder abduction and forward elevation appear much later.^{2,10} Eventually, a SAN injury can lead to atrophy of the trapezius. However, muscle asymmetry may not be obvious, especially in bilateral iatrogenic SAN injuries. In our experience, these patients benefit from PT. However, the optimum type and timing of PT requires further investigation. Development of best-practice guidelines in terms of management is necessary.

CONFLICT OF INTEREST:

The authors declared no conflict of interest.

PATIENT'S CONSENT:

The consent of the patient, on which this case was based, was taken prior to the writing of the manuscript.
